(54) Title: REPLACEMENT THERAPY FOR DENTAL CARIES

(57) Abstract

Recombinant *Streptococcus mutans* strains characterized by a deficiency in lactic acid production and production of a recombinant alcohol dehydrogenase (ADH) are described. These recombinant *S. mutans* strains are suitable for use in a method for preventing treating dental caries.

REPLACEMENT THERAPY FOR DENTAL CARIESStatement as to Federally Sponsored Research

5 This invention was made at least in part with funds from the Federal government through a grant from the National Institute of Dental Research, Public Health Service grant no. DEO4529. The government may have certain rights in this invention.

Background of the InventionField of the Invention

This invention relates to methods and compositions for the prevention of dental caries.

10 Description of Related Art

The ability of a given bacterium to colonize a host is determined by a number of factors such as the bacterium's metabolic needs, and the interactions of the bacterium with the pre-existing bacterial flora. Bacterial interactions can be generally classified as either "positive" or "negative." In positive interactions, an "effector" bacterial strain alters the microenvironment to promote colonization of a second, "target" organism. In "negative" interactions, the effector strain alters the microenvironment in a manner that decreases or completely prevents target bacterium colonization. Negative interactions between competing bacteria during host colonization are commonly termed bacterial interference.

20 Therapeutic regimens which take advantage of bacterial interference to replace a pathogenic bacterial strain with a non-pathogenic, effector strain are termed replacement therapies. Successful replacement therapy requires an effector strain that: 1) is non-pathogenic, 2) alters the microenvironment so as to prevent colonization or outgrowth of pathogenic organisms, 3) persistently colonizes the host at risk to prevent reinfection by the target pathogenic organism, and aggressively displace the pathogenic organism from the tissues at risk where the pathogen is part of the host's indigenous flora.

25 It is well known that dental caries are caused by bacteria that colonize the oral cavity. The principle dental caries-causing bacterial pathogen in humans is the bacterium *Streptococcus mutans*. The characteristic features of *S. mutans* implicated in

- 2 -

cariogenesis include its ability to produce lactic acid, as well as its ability to accumulate on tooth enamel (i.e., plaque formation) (Gibbons et al., 1969, *J. Bacteriol.*, 98:341-346; Makinen et al., 1972, *Int. Dent. J.*, 22:362-386; and Jordan, 1965, *Ann. N.Y. Acad. Sci.*, 131:905-912). Application of the principles of
5 replacement therapy would require the isolation of a non-cariogenic effector strain of *S. mutans*, e.g., a *S. mutans* strain deficient in lactic acid synthesis. The progress in the application of replacement therapy to dental caries has been recently reviewed (Hillman et al., 1989, In: New Biotechnologies in Oral Research, H.M. Myers, ed., S. Karger, Basel, Switzerland, pgs. 1-17).

10 Generation of a lactic acid-deficient *S. mutans*, and thus a strain suitable for replacement therapy for dental caries, has met with considerable difficulty. Defects in lactic acid synthesis are lethal to *S. mutans*. Abhyankar et al. (1985, *J. Dent. Res.*, 64:1267-1271) generated a lactate dehydrogenase(LDH)-deficient *S. mutans* mutant by chemical mutagenesis using an atypical *S. mutans* strain that contained
15 a preexisting (spontaneous) mutation affecting pyruvate metabolism. However, the chemically-induced and the spontaneously-generated mutations in this strain remain uncharacterized. Moreover, chemically-induced, uncharacterized mutations can revert to wild-type, and thus the pathogenic, cariogenic phenotype. Subsequent attempts to produce LDH-deficiencies in other *S. mutans* strains have failed
20 (Hillman et al., 1994, *Infect. Immun.*, 62:60-64; Chen et al., 1994, *J. Bacteriol.*, 176:1542-1545).

There is a clear need in the field for a stable, lactic acid-deficient, non-cariogenic strain of *S. mutans* that is suitable for use in a replacement therapy in the prevention and/or treatment of dental caries.

25

Summary of the Invention

30

The invention is based on the discovery that lactic acid-deficient *Streptococcus mutans* strains can be generated by introducing a mutation in a gene involved in the lactic acid synthesis pathway, and preventing the lethality of this mutation by introducing a recombinant alcohol dehydrogenase (*adh*) gene into the lactic acid-deficient bacterium. The recombinant *adh* prevents accumulation of metabolites (e.g., pyruvate) in the bacterium, thus circumventing the lethality of the lactic acid

- 3 -

deficiency. This strategy can be applied to production of a *S. mutans* strain suitable for use in a replacement therapy for dental caries.

In general, the invention features methods and compositions for the prevention and/or treatment of dental caries in a dental caries-susceptible host.

- 5 In one aspect, the invention features a recombinant *Streptococcus mutans* strain characterized by a deficiency in lactic acid production (e.g., due to elimination of lactate dehydrogenase activity) and, in its stead, production of a recombinant alcohol dehydrogenase (ADH). "Deficiency in lactic acid production" or "lactic acid deficient" means that the recombinant *S. mutans* strain produces substantially decreased amounts of lactic acid relative to wild-type *S. mutans*. Preferably, a "lactic acid deficient" recombinant *S. mutans* produces no detectable lactic acid. The invention also features methods for producing the recombinant strains of the invention.
- 10 A preferred recombinant *S. mutans* strain is characterized by: 1) a deficiency in lactic acid production; 2) production of a recombinant alcohol dehydrogenase; and 15 3) production of a bacteriocin having antibacterial activity against a bacteriocin-susceptible *Streptococcus mutans* strain, and 4) optionally can be auxotrophic (e.g., auxotrophic for D-alanine).
- 15 Additional preferred recombinant *S. mutans* strains are deficient in lactic acid production, produce a recombinant alcohol dehydrogenase, and are auxotrophic (e.g., auxotrophic for D-alanine).
- 20 The invention additionally features pharmaceutical compositions composed of a recombinant lactic acid-deficient, recombinant ADH-producing *S. mutans* strain and a pharmaceutically acceptable carrier.
- 25 The invention also features a method of reducing the incidence or severity of dental caries in a dental caries-susceptible host by orally administering to a dental caries-susceptible host a recombinant *Streptococcus mutans* strain having 1) a recombinant alcohol dehydrogenase gene and 2) a deficiency in lactic acid production, in an

- 4 -

amount effective for replacement of dental caries-causing *Streptococcus mutans* host strains in the oral cavity of the host.

The invention additionally features a composition for maintenance of a D-alanine bacterial auxotroph (e.g., a *S. mutans* D-alanine auxotroph) in the oral cavity of a host comprising a D-alanine bacterial auxotroph-maintaining amount of D-alanine.

One advantage of the invention is that the recombinant *S. mutans* strains 1) are lactic acid deficient, and thus will not cause dental caries, and 2) will effectively replace dental caries-causing strains of *S. mutans* in the oral cavity of the host.

Another advantage is that, where the recombinant *S. mutans* is a D-alanine auxotroph, colonization of the strain can be controlled by administration of D-alanine.

Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof, and from the claims.

Brief Description of the Drawings

Fig. 1 shows the amino acid (SEQ ID NO:1) and DNA sequence (SEQ ID NO:2) of *Z. mobilis* alcohol dehydrogenase II.

Fig. 2 shows the effect of glucose on the growth, survival, and intracellular pyruvate concentration of the *Streptococcus mutans* strains CH4ts and NG8 (control). Symbols: NG8 with glucose, —□—; NG8 without glucose, —○—; CH4ts with glucose, —○—; CH4ts without glucose, —△—.

Fig. 3 shows the effects of glucose concentration and temperature upon continuous culture of *Streptococcus mutans* strain CH4ts at a 10% dilution rate. Detailed Description

- 5 Dental caries are caused by the production and accumulation of lactic acid by *Streptococcus mutans* that normally colonizes the oral cavity. However, since mutations in the lactic acid production pathway of *S. mutans* are lethal for the bacterium, introduction of lactic acid deficient *S. mutans* into the oral cavity to replace lactic acid-producing *S. mutans* strains has not been possible.
- 10 The invention is based on the discovery that viable, lactic acid-deficient *Streptococcus mutans* strains can be generated by transforming the strains with nucleic acid encoding a recombinant alcohol dehydrogenase (ADH), and introducing a mutation in the lactic acid synthesis pathway to render the recombinant ADH-producing strain lactic acid deficient. The recombinant ADH prevents accumulation 15 of metabolites in the bacterium, thus circumventing the lethality of the lactic acid deficiency. This strategy can be applied to production of recombinant *S. mutans* strains suitable for use in a replacement therapy for dental caries.

Recombinant *Streptococcus mutans* strains of the invention

- A "recombinant *Streptococcus mutans* strain" is a non-naturally occurring strain of *S. mutans* that has been generated using any of a variety of recombinant nucleic acid techniques (i.e., techniques involving the manipulation of DNA or RNA). In general, a recombinant *Streptococcus mutans* strain of the invention is minimally characterized by: 1) a deficiency in lactic acid production, and 2) production of a recombinant alcohol dehydrogenase (ADH).
- 25 Recombinant *S. mutans* strains are preferably further characterized by production of a bacteriocin having antibacterial activity against a bacteriocin-susceptible *S. mutans* strain. "Bacteriocin," as used herein, means the specific bacteriocin or bacteriocin-like toxin produced by *S. mutans* strain JH1000 (Hillman et al., 1984, *Infect. Immun.*, **44**:141-144). The bacteriocin of *S. mutans* JH1000 has an apparent molecular weight of less than about 1,000 Da, and has antibacterial activity against 30

- 6 -

bacteriocin-susceptible *S. mutans* strains. Production of the bacteriocin thus provides the *S. mutans* with a selective advantage over non-bacteriocin-producing *S. mutans* strains normally present in the oral cavity. The bacteriocin, when present in a recombinant *S. mutans* strain of the invention, eliminates the resident, 5 bacteriocin-susceptible *S. mutans* strains, thus interfering with colonization of bacteriocin-susceptible strains and promoting recombinant *S. mutans* colonization of the oral cavity.

Because it may be desirable to control oral cavity colonization by the recombinant *S. mutans* strains of the invention, the recombinant *S. mutans* strain is preferably an 10 auxotroph for an organic substance not normally present in the oral cavity of the mammalian host, more preferably an auxotroph for a D-amino acid, even more preferably a D-alanine auxotroph. Colonization of auxotrophic strains can be controlled by regulating the amount of the organic substance for which the strain has an auxotrophy. Thus, if the need arises to rid the host of recombinant *S. mutans*, 15 colonization can be terminated by withholding administration of the specific organic substance for which the strain is auxotrophic.

Thus, recombinant *S. mutans* strains of the invention are characterized by: 1) a lactic acid deficiency, and 2) production of a recombinant ADH, and can be further characterized by 3) bacteriocin production, and/or 4) an auxotrophy for a specific 20 organic substance, preferably a D-amino acid, more preferably D-alanine. Production of each of the recombinant *S. mutans* strains of the invention will now be described in detail.

Parent *Streptococcus mutans* strains for use in production of recombinant *S. mutans* strains of the invention

The *Streptococcus mutans* strain for use in the production of recombinant *S. mutans* strains of the invention can be any *S. mutans* strain. Preferably, the *S. mutans* strain used to produce recombinant *S. mutans* strains of the invention have a selective advantage over wild-type *S. mutans* strains that normally colonize the oral cavity. The selective advantage can be conferred by any of a variety of characteristics (e.g., 25 production of an antibacterial compound, relative metabolic needs, relative growth rate, production of scavengers for metabolites) that promote oral cavity colonization by the strain, and replacement of the resident strain colonizing the oral cavity.

- 7 -

Preferably, colonization by the recombinant *S. mutans* strains of the invention will not substantially disrupt colonization by other, non-*S. mutans* strains (e.g., normal bacterial flora not associated with cariogenesis). For example, infection of human volunteers with a variant strain of *S. mutans* JH1000 that produced enhanced levels of bacteriocin resulted in replacement of the resident, cariogenic *S. mutans* strains (presumably in part due to bacteriocin production by the JH1000 strain) without effect upon other resident Gram positive species of the oral cavity (Hillman et al., 1987, *J. Dent. Res.*, 66:1092-1094).

Preferably, the *S. mutans* strain produces the bacteriocin of *S. mutans* JH1000. More preferably, the recombinant *S. mutans* strains are generated from *S. mutans* JH1000 variants that produce greater amounts of the bacteriocin relative to the amount produced by *S. mutans* JH1000. A "variant" is a genetically modified bacterium that exhibits a phenotypic alteration relative to the parent strain from which it was derived. The phenotypic alteration can result from any of a variety of genetic lesions, such as an alteration in: 1) the promoter operably linked to the structural gene (e.g., to effect an increase in gene transcription); and/or 2) the structural gene encoding a specific product (e.g., such that the product has enhanced activity). A genetic lesion is an alteration in a wild-type nucleotide sequence that results in a phenotypic alteration in the bacterium.

For example, a "bacteriocin variant" of *S. mutans* JH1000 is a bacterium that has increased bacteriocin activity relative to the *S. mutans* JH1000 parent strain. Preferably, the bacteriocin activity of the *S. mutans* JH1000 variant is increased relative to the bacteriocin activity of the parent *S. mutans* strain, preferably by about 10-fold, preferably about 1.5-fold to 5-fold, more preferably about 2-fold to 4-fold, generally about 3-fold relative to the parent *S. mutans* JH1000 strain. Increased bacteriocin activity of these variants can result from an increased level of bacteriocin production relative to the parent strain, and/or production of a bacteriocin having enhanced antibacterial activity relative to wild-type *S. mutans* bacteriocin.

"Variants" can be generated by a variety of methods well known in the art such as mutagenesis (i.e., exposure of the bacterium to a mutagen), selection of spontaneous mutants, or genetic manipulation using recombinant techniques. Mutagenesis can be accomplished by exposing the bacterium to ultraviolet light, or

- 8 -

any of a variety of chemical mutagens, according to methods well known in the art (e.g., ethyl methanesulfonate (EMS), nitrous acid, hydroxylamine, nucleotide analogs (e.g., 5-bromouracil, 2-aminopurine), or intercalating agents (e.g., acridines). Methods for generation of bacterial mutants are well known in the art (see, for example, Sambrook et al., 1989, *Molecular Cloning: A Laboratory Manual*, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY).

"Spontaneous mutations" are mutations that arise naturally, i.e., without direct genetic manipulation by man, or by exposure to a mutagen. Selection of spontaneous mutants can be accomplished by culturing the strain and selecting the desired variants by, for example, the variant bacterium's production or overproduction of a specific factor, e.g., bacteriocin. Methods for selection of spontaneous mutants are well known in the art (see, for example, Sambrook et al., *supra*).

Methods for producing variants using recombinant techniques are well known in the art (see, for example, Sambrook et al., 1989, *supra*). For example, *S. mutans* JH1000 variants having increased bacteriocin activity can be generated by expression of multiple copies of bacteriocin-encoding DNA, and/or mutation of the bacteriocin promoter to provide higher levels of transcription.

20 Alcohol dehydrogenase genes

Because defects in lactic acid synthesis are lethal for *S. mutans* (Hillman et al., 1994, *Infect. Immun.*, 62:60-64; Hillman et al., 1994, *J. Bacteriol.*, 176:1542-1545), the defect in the recombinant, lactic acid-deficient *S. mutans* strains must be complemented by the production of a recombinant alcohol dehydrogenase (ADH). Production of the recombinant ADH prevents accumulation of metabolites, e.g., pyruvate, that otherwise causes the death of lactic acid-deficient *S. mutans*.

"Production of a recombinant ADH" means that the recombinant *S. mutans* strain expresses a functional ADH enzyme that has been introduced into the *S. mutans* strains using recombinant DNA techniques (i.e., the *S. mutans* has been transformed with DNA encoding an ADH enzyme). "Transformation" means a permanent (i.e., stable) genetic change induced in a cell following incorporation of new DNA (i.e., DNA exogenous to the cell).

- 9 -

- The ADH-encoding DNA can be derived from any organism, preferably from a bacterium, more preferably from *Zymomonas mobilis* or *Streptococcus rattus*, even more preferably from *Z. mobilis*. The ADH-encoding DNA can be derived from 5 *S. mutans*, so that introduction of the ADH-encoding DNA, in combination with the native *S. mutans adh* gene, provides for multiples copies of ADH-encoding DNA in the *S. mutans* genome. Alternatively, the recombinant ADH can be generated by introducing a mutation in the regulatory mechanism of the *S. mutans adh* gene (e.g., a mutation in the *adh* promoter to provide increased transcription of the *adh* gene). 10 Preferably, the recombinant ADH is alcohol dehydrogenase II of *Z. mobilis*, which has been cloned and sequenced (Genbank Accession No. M15394; Conway et al., 1987, *J. Bacteriol.*, 169:2591-2597, incorporated herein by reference). The amino acid (SEQ ID NO:1) and DNA (SEQ ID NO:2) sequences of *Z. mobilis* alcohol dehydrogenase II are shown in Fig. 1.
- 15 Methods for identification, cloning, stable transformation, and expression of DNA fragments encoding a DNA of interest (e.g., ADH) are routine and well known in the art (see, for example, Sambrook et al., 1989, Molecular Cloning: A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). For example, isolation of DNA encoding ADH can be performed by PCR amplification 20 of the sequence from genomic DNA, or from a preexisting clone of the gene. Expression of recombinant ADH can be accomplished by operably linking the *adh* structural gene to a promoter that facilitates expression in *S. mutans* (e.g., *spaP* or the native *ldh* promoter).
- 25 Production of a functional ADH can be assayed by, for example, using conventional ADH activity assays (e.g., assays for NAD-dependent oxidation of ethanol) that are well known in the art (Neal et al., 1986, *Eur. J. Biochem.*, 154:119-124, incorporated herein by reference).
- Generation of lactic acid-deficient *S. mutans*
"Lactic acid deficient" or "deficiency in lactic acid production" means that the 30 *S. mutans* strain produces substantially decreased amounts of lactic acid relative to wild-type *S. mutans*. Preferably, a "lactic acid deficient" recombinant *S. mutans* produces no detectable lactic acid.

- 10 -

Recombinant *S. mutans* strains of the invention are lactic acid deficient as a result of a defect in the lactic acid synthesis pathway. A "defect" is an alteration in the DNA encoding the gene that prevents expression of a functional gene product. "Defects" include alterations that result in inhibition of, or a substantial decrease in, gene transcription and/or translation. "Defects" also include alterations in a structural gene, such that the transcribed and translated gene product is non-functional, or functions at a substantially decreased level relative to the wild-type gene product.

A "defect in the lactic acid synthesis pathway" is a genetic defect that prevents, or substantially decreases, production of lactic acid. Lactic acid synthesis pathway defects can include, for example, genetic lesions in an enzyme that facilitates lactic acid synthesis, and/or a promoter operably linked to a structural gene encoding an enzyme required for lactic acid synthesis. Preferably, the defect in the lactic acid synthesis pathway is due to a defect in the gene encoding lactate dehydrogenase (*ldh*) (e.g., a defect in the *ldh* structural gene, and/or a defect in the promoter operably linked to the *ldh* structural gene). *S. mutans* having a defect in LDH are termed LDH⁻ strains.

The defect in the lactic acid synthesis pathway can be introduced by mutagenesis (i.e., exposure of the bacterium to a mutagen), selection of spontaneous mutants, or genetic manipulation using recombinant techniques. As discussed above, each of these techniques are well known in the art (see, for example, Sambrook et al., *supra*). Preferably, the lactic acid synthesis pathway defect is introduced using recombinant techniques, e.g., introduction of a defective *ldh* structural gene into the bacterium and subsequent site-specific recombination to replace the wild-type *ldh* with the defective *ldh*. The *S. mutans* *ldh* gene has been cloned, its nucleotide sequence determined (GenBank accession number M72545), and the recombinant *ldh* gene expressed in *Escherichia coli* (Duncan et al., 1991, *Infect. Immun.*, 59:3930-3934; Hillman et al., 1990, *Infect. Immun.*, 58:1290-1295, each incorporated herein by reference).

Production of auxotrophic, recombinant *S. mutans* strains

In the event that it becomes desirable to rid the host of the recombinant *S. mutans* colonizing the oral cavity, the infecting recombinant *S. mutans* strain is preferably an auxotroph. An "auxotroph" is a bacterium that requires a source of a specific organic

- 11 -

substance(s), in addition to a source of carbon, in order to grow. For example, a "D-alanine auxotroph" is a bacterium that cannot grow without a source of D-alanine. Although auxotrophs can often persist (i.e., survive without growth) for a short period in the absence of the required organic substance, maintenance of auxotrophic colonization requires periodic supplements with that organic substance.

For example, D-alanine auxotrophic bacteria require periodic D-alanine supplements in order to grow and maintain colonization of a niche, such as the oral cavity. Because mammals do not normally produce D-amino acids, and D-alanine is not normally secreted by organisms of the normal flora, D-alanine cannot be acquired by a D-alanine auxotroph from the normal milieu of the host's oral cavity. Thus, use of auxotrophs in the therapeutic method of the invention provide the advantage that oral colonization by the recombinant *S. mutans* can be interrupted by withholding the specific organic supplement, e.g., the D-alanine supplement.

Bacterial auxotrophs can be generated using a variety of techniques well known in the art, such as chemical mutagenesis, selection of spontaneous mutants, and/or recombinant techniques (e.g., transposon mutagenesis, replacement by recombination with a defective or non-functional gene) (see, for example, Sambrook et al., *supra*). Preferably auxotrophic *S. mutans* strains are generated by either selection of spontaneous mutants, or by recombinant methods (e.g., introduction of a defect in a synthetic pathway for a D-amino acid). Preferably, D-alanine auxotrophic *S. mutans* strains are generated by introduction of a defect in the gene encoding alanine racemase, the enzyme that converts L-alanine to D-alanine. The genes encoding the alanine racemase of several different bacteria have been cloned (*Bacillus stearothermophilus*, Tanizawa et al., (1988) *Biochem.* 27:1311-16; *Bacillus subtilis*, Ferrari et al., *Subtilis*, (1985) *Biotechnol. (NY)* 3:1003-7; *E. coli*, Lobocka, (1994) *J. Bacteriol.* 176:1500-10; *Salmonella typhimurium*, Galakatos et al., (1986) *Biochem.* 23:3255-60; and *Salmonella typhimurium*, Wasserman et al., (1984) *Biochem.* 23:5182-7).

Pharmaceutical compositions containing recombinant *S. mutans* of the invention
A "pharmaceutical composition" is a composition appropriate for oral administration of a recombinant *S. mutans* strain of the invention to a dental caries-susceptible patient. In general, pharmaceutical compositions of the invention are composed of

- 12 -

- a recombinant *S. mutans* strain and a pharmaceutically acceptable carrier. A "pharmaceutically acceptable carrier" means a vehicle for delivery of a recombinant *S. mutans* strain to the oral cavity of the host, in which the vehicle is compatible with both bacterial cell and host cell viability. Pharmaceutically acceptable carriers suitable for use in the administration of viable recombinant *S. mutans* strains of the invention are well known to those skilled in the art. Selection of the pharmaceutically acceptable carrier will depend upon a variety of factors including the recombinant *S. mutans* strain to be administered, and the formulation used to deliver the recombinant *S. mutans*.
- Pharmaceutically acceptable carriers suitable for use with the recombinant *S. mutans* strains of the invention include, but are not limited to, buffered saline solutions (e.g., phosphate-buffered saline), pharmaceutically acceptable culture media (e.g., Luria broth, brain-heart infusion broth (BHI)), or other solutions which maintain the viability of the bacterium. Additionally, such pharmaceutically acceptable carriers may be aqueous or non-aqueous solutions, suspensions, and emulsions. A variety of pharmaceutically acceptable carriers suitable for oral administration of viable or lyophilized bacteria are well known in the art (see, for example, Remington's Pharmaceutical Sciences, 18th ed., Gennaro, ed., 1990, Mack Publishing Co., Easton, PA, incorporated herein by reference; and the pharmaceutical composition LACTINEX™, a commercially available formulation for oral administration of viable *Lactobacillus*).
- The recombinant *S. mutans* strains of the invention can be formulated in any of a variety of compositions suitable for oral administration. For example, the recombinant *S. mutans* strain can be formulated for administration as a lyophil or cell paste prepared from a recombinant *S. mutans* culture, or the recombinant *S. mutans* culture can be directly administered to the oral cavity. The recombinant *S. mutans* strain can also be administered in the form of a mouthwash, toothpaste, floss, chewing gum, or chewable tablet.
- The pharmaceutical composition can additionally contain nutrients to maintain the viability of the bacterium in the composition. The pharmaceutical composition can also contain flavoring agents, coloring agents, fragrances, or other compounds which increase the palatability of the composition and/or enhance patient compliance

- 13 -

without compromising the effectiveness of the composition. Methods for preparation of formulations for oral administration are well known in the art (see, for example, Remington's Pharmaceutical Sciences, 18th ed., *supra*, incorporated herein by reference).

5 Compositions for maintenance of auxotrophic recombinant *S. mutans* of the invention
Colonization of the oral cavity by recombinant, auxotrophic *S. mutans* strains must
be maintained by periodic administration of the organic substance for which the
strain is auxotrophic. In the prolonged absence of the organic substance, the
auxotrophs will cease growth and the strain can no longer persistently colonize the
10 oral cavity. For example, in the absence of D-alanine, D-alanine auxotrophs undergo
lysis due to a weakened cell wall. The use of auxotrophic recombinant *S. mutans* in
the therapeutic method of the invention provides a "fail safe" mechanism for
eliminating the strain in the event of any undesirable side-effect. However, because
15 the recombinant *S. mutans* strains of the invention are similar to the indigenous
S. mutans strains that normally colonize the oral cavity, the likelihood of undesirable
side-effects is low.

Maintenance of oral cavity colonization by the auxotrophic, recombinant *S. mutans* strains of the invention can be achieved by oral administration of an auxotroph-maintaining amount of the organic substance for which the bacterium is auxotrophic.
20 A "bacterial auxotroph-maintaining amount" is an amount of an organic substance sufficient to maintain viability of the bacterial auxotroph in the oral cavity. For example, where the recombinant *S. mutans* is auxotrophic for D-alanine, a "D-alanine bacterial auxotroph-maintaining amount" is an amount of D-alanine sufficient for survival of the D-alanine auxotrophic strain in the host's oral cavity. In
25 general, a single dose of a D-alanine bacterial auxotroph-maintaining amount of D-alanine contains from about 1 mg to 100 mg, preferably from about 5 mg to 75 mg, more preferably from about 10 mg to 50 mg, even more preferably from about 20 mg to 25 mg of D-alanine. The concentration of D-alanine in the pharmaceutical composition in the form of a solution ranges from about 0.01 mg/ml to 167 mg/ml
30 (the latter being a saturated solution of D-alanine in water at 25°C), preferably from about 0.1 mg/ml to 50 mg/ml, more preferably from about 1 mg/ml to 25 mg/ml. The concentrations of D-alanine in the pharmaceutical composition can vary according to the carrier used and the saturation point of D-alanine in that specific carrier.

- 14 -

The organic substance required for maintenance of the auxotrophic, recombinant *S. mutans* in the oral cavity can be formulated in a variety of ways. For example, where the recombinant *S. mutans* is auxotrophic for D-alanine, the composition for maintenance of the D-alanine auxotroph can be formulated as a mouthwash, chewing gum, dental floss, toothpaste, chewable tablet, or any other formulation suitable for oral administration to the host's oral cavity. In addition to the organic substance (e.g., D-alanine), the composition can additionally contain flavoring agents, coloring agents, fragrances, or other compounds which increase the palatability of the composition and/or enhance patient compliance without compromising the effectiveness of the organic substance contained in the composition.

The pharmaceutical compositions formulated for oral administration of the recombinant *S. mutans* strains of the invention and, where desired, their maintenance in the oral cavity must be developed within the intrinsic characteristics of the oral cavity and any desirable normal bacterial flora colonizing the oral cavity. Methods for preparation of formulations suitable for oral administration are well known in the art (see, for example, Remington's Pharmaceutical Sciences, 18th ed., Gennaro, ed., 1990, Mack Publishing Co., Easton, PA, incorporated herein by reference).

20 Administration

The recombinant *S. mutans* strains of the invention can be administered to any dental caries-susceptible host, preferably a host in which *S. mutans* can colonize the oral cavity, preferably a mammalian host (e.g., human, canine, equine, feline, ovine, etc.), more preferably a human host. The recombinant *S. mutans* strains can be administered to the host at any age, e.g., childhood, adolescence, or adulthood.

The recombinant *S. mutans* strains of the invention can be orally administered in a variety of ways. For example, the recombinant *S. mutans* strains may be administered in the form of suspensions, chewable tablets, pills, capsules, sustained release formulas (e.g., an oral implant containing the recombinant *S. mutans* strain) or lyophil powders. The recombinant *S. mutans* strains can also be administered by direct application of a lyophil, culture, or cell paste to the teeth of the patient. Any mode of administration is suitable as long as the therapeutic composition is applied

- 15 -

to the oral cavity. Preferably, the recombinant *S. mutans* is administered by applying a bacterial cell suspension directly to the teeth of the patient, e.g., by brushing and flossing.

In general, the amount of recombinant *S. mutans* administered to the patient will be an amount effective for replacement of dental caries-causing *S. mutans* strains in the oral cavity of the host. "An amount effective for replacement of dental caries-causing *S. mutans* strains in the oral cavity of the host" means an amount effective for oral cavity colonization by the recombinant *S. mutans* strain, and elimination of the resident, lactic acid-producing, dental caries-causing *S. mutans* strains (e.g., by competition between the bacteria for nutrients and/or by the production of a bacteriocin by the recombinant *S. mutans* strain). The term "unit dose" when used in reference to a pharmaceutical composition of the present invention refers to physically discrete units suitable as unitary dosage for the subject, each unit containing a predetermined quantity of active material (e.g., viable recombinant *S. mutans*) calculated to produce the desired therapeutic effect in association with the required diluent; i.e., carrier, or vehicle.

Specific dosages can vary widely according to various patient variables including size, weight, age, disease severity (e.g., the tenacity and/or number of lactic acid-producing, dental caries-causing resident *S. mutans*) and responsiveness to therapy (e.g., the susceptibility of the host's oral cavity to colonization). Methods for determining the appropriate route of administration and dosage are generally determined on a case-by-case basis by the attending dentist or other clinician. Such determinations are routine to one of ordinary skill in the art (see, for example, Remington's Pharmaceutical Sciences, 18th ed., Gennaro, ed., Mack Publishing Company, Easton, PA, 1990).

In general, the number of recombinant *S. mutans* administered to the patient will range from about 10^2 to 10^{15} bacteria, preferably from about 10^3 to 10^{14} bacteria, more preferably from about 10^5 to 10^{12} bacteria, normally about 10^{11} bacteria. Dosages appropriate for administration can be readily extrapolated from dosages sufficient for *Streptococcus* spp. colonization of the oral cavity in an animal model, e.g., *S. rattus* colonization of the oral cavity of rats. Appropriate dosages can also be estimated from dosages found appropriate for colonization of the human oral

- 16 -

cavity by the bacteriocin-producing strain *S. mutans* JH1000, and variants thereof that express varying levels of bacteriocin activity (Hillman et al., 1987, *J. Dent. Res.*, 66:1092-0194, incorporated herein by reference).

Multiple doses of the recombinant *S. mutans* strains can be administered to achieve
5 oral cavity colonization and replacement of the resident, dental caries-causing
S. mutans strains of the host. In general, the recombinant *S. mutans* strains of the
invention need only be administered to the patient one time. Where the recombinant
10 *S. mutans* strain is an auxotroph, colonization of the strain must be maintained by
administration of a composition containing the appropriate organic substance. For
example, where the recombinant *S. mutans* strain is a D-alanine auxotroph,
D-alanine must be administered for persistent oral cavity colonization. D-alanine, or
other appropriate organic substrate, is generally administered at least once a week,
preferably at least once a day, more preferably at least twice a day, and can be
administered as part of the patient's routine dental care, e.g., as a component of a
15 toothpaste, floss, or mouthwash.

Successful colonization of the host's oral cavity by the recombinant *S. mutans* strain
can be established by culturing the bacteria of the patient's oral cavity, and
identifying the recombinant strain by, for example, recombinant ADH production,
20 bacteriocin production, ELISA, growth on selective pH indicator media, or other
methods well known in the art for bacterial strain identification.

The following examples are intended to illustrate but not limit the invention. While
they are typical of those that might be used, other procedures known to those of
ordinary skill in the art may alternatively be used.
25

EXAMPLES

Example 1. Materials and Methods

Bacterial strains, plasmids, and growth conditions

Methods for generating *S. mutans* strain CH4ts (Chen et al., 1994, *J. Bacteriol.*,
30 176:1542-1545) and isolating of *S. mutans* strain NG8 (Lee et al., 1989, *Infect.*
Immun., 57:3306-3313) have been described previously. *E coli* strain DH5 α , used

- 17 -

for cloning, is publicly available. Construction of the plasmid pLOI276 (Conway et al., 1987, *J. Bacteriol.*, 169:949-954) containing the cloned *Zymomonas mobilis* pyruvate decarboxylase (PDC) gene, the plasmid pLOI286 (Conway et al., 1987, *J. Bacteriol.*, 169:2591-2597) containing the cloned *Z. mobilis* alcohol dehydrogenase II (*adh*) gene, the pCR2-based plasmid pCR3-8 containing the cloned *S. mutans* *spaP* gene (Crowley et al., 1995, *J. Dent. Res.*, 74, abstract no. 1511), and the plasmid pVA981 containing a tetracycline resistance gene derived from *S. mutans* (Tobian et al., 1984, *J. Bacteriol.*, 160:556-563) have been previously described. Each of the references cited above are hereby incorporated by reference for their respective descriptions of the construction of the indicated plasmids, and the generation or isolation of the recited strains.

batch and continuous cultures of CH4ts were grown in the defined medium of Carlsson (Carlsson et al., 1970, *Caries Res.*, 4:297-304) supplemented with 0.5% tryptone and 1% glucose. Cells for assay of ADH activity were grown in Todd-Hewitt broth supplemented with 1% glucose. Ampicillin (50 µg/ml), tetracycline (10 µg/ml), and erythromycin (5 µg/ml) were used where appropriate.

Assays of cultures

Samples of batch and continuous cultures were removed at indicated times, and their pH and absorbance at 550 nm determined. Cells were removed by centrifugation at 4°C and the resulting cell-free liquors were assayed enzymatically (Sigma Chemical Co., St. Louis, MO) for glucose, ethanol, and lactic acid and by gas-liquid chromatography (Hillman et al., 1987, *Infect. Immun.*, 55:1399-1402) for acetoin. The pelleted cells were washed once by centrifugation with phosphate-buffered saline (PBS) and assayed chemically (Friedmann et al., 1957, In: S.P. Colowick and N.O. Kaplan (ed), *Methods in Enzymology*, Academic Press, Inc., New York, p. 414-418) to determine intracellular pyruvate concentrations. The data presented in the figures are the averages of duplicate experiments.

Assay for alcohol dehydrogenase activity

Cells from 200 ml overnight cultures of *E. coli* and *S. mutans* strains were recovered by centrifugation at 4°C and washed twice in 100 mM KPO₄ buffer (pH 8.5). The cell pellets were resuspended in 1 ml of buffer and broken by passage through a French press at 15,000 psi. Cell debris was removed by centrifugation at 4°C for 30 min.

- 18 -

The cell-free extracts were kept on ice and assayed for the NAD-dependent oxidation of ethanol according to the methods of Neale et al. (Neal et al., 1986, *Eur. J. Biochem.*, 154:119-124).

Assay for lactate dehydrogenase activity

5 LDH activity assays were performed as previously described (Hillman et al., 1990, *Infect. Immun.*, 58:1290-1295). Briefly, LDH activity was assayed as the fructose-1,6-diphosphate (FDP)- and pyruvate-dependent oxidation of NADH measured at 340 nm with a spectrophotometer. The reaction mixture contained 100 µmol potassium phosphate, pH 6.2, 0.2 µmol NADH, 10 µmol sodium pyruvate, 10 1.5 µl of the sample to be tested in a final volume of 1 ml. Background levels of activity were measured for 1 min, and then the reaction was initiated by the addition of 20 µmol FDP.

Example 2: Cloning of the *Zymomonas mobilis adh* structural gene for expression in *S. mutans*

15 The plasmid pADH contains the *Z. mobilis adh* open reading frame fused to the regulatory sequences of the *S. mutans spaP* gene. pADH was constructed by first digesting plasmid pCR3-8 with *SacI* and *DraIII*, and then treating the digested DNA with mung bean nuclease to remove the entire *spaP* gene except for its promoter, ribosome binding site, and 52 bases of the 5' end of the open reading frame. A 20 4.2 kb fragment of the linearized pCR3-8 plasmid was recovered by agarose gel electrophoresis.

Polymerase chain reaction (PCR) was used to amplify the entire open reading frame of the *Z. mobilis adh* gene except for its translation start codon (ATG) plus one additional (G) base from the plasmid pLOI286 using forward 25 (5' CTTCTTCAACTTTTATATTCCCTTCG (SEQ ID NO:3)) and reverse (5' CGGAGGCATTGTTTG (SEQ ID NO:4)) synthetic primers. The amplified fragment was recovered by agarose gel electrophoresis, treated with mung bean nuclease and polynucleotide kinase, and ligated into the pCR3-8 fragment to form the translational fusion with *spaP*. The resulting plasmid, pADH was used to transform *Escherichia coli* DH5 α cells. Transformants of DH5 α were selected on LB 30

- 19 -

medium containing ampicillin. The proper size and orientation of the pADH insert were confirmed by restriction enzyme analysis.

In preparation for cloning into *S. mutans*, pADH was converted to pADH-tet by inserting the 3.5 kb *HincII* fragment of pVA981 containing a tetracycline resistance gene derived from *S. mutans* (Tobian et al., 1984, *J. Bacteriol.*, 160:556-563) into the *Scal* site of pADH. The pADH-tet construct was used to transform DH5 α , and transformants selected on Luria broth (LB) with tetracycline were tested for sensitivity to ampicillin. *S. mutans* was then transformed with pADH-tet using methods of Perry and Kuramitsu (Perry et al., 1981, *Infect. Immun.*, 32:1295-1297).

10 Example 3: Effects of glucose concentration upon growth of CH4ts and NG8 in batch cultures

Overnight batch cultures of CH4ts (*ldh^{ts}*) and its parent *S. mutans* NG8, were grown at 30°C. CH4ts contains a temperature-sensitive mutation of lactate dehydrogenase (LDH). The LDH of CH4ts behaves as wild-type at 30°C, but upon a culture temperature shift to 42°C, the heat-labile LDH is inactive. This strain thus allows experiments to determine the role of LDH in the lethality of LDH-mutants of *S. mutans*. Washed cells were diluted 1:1000 in fresh medium with and without glucose and incubated in a 42°C water bath. At time points indicated in Fig. 2 (Panel A), viable cell counts were determined by spreading samples on brain heart infusion (BHI) plates and incubating the plates at 30°C. The results show that in the absence of glucose (dashed lines), CH4ts (open triangles) and NG8 (open circles) behaved identically: growth ceased after 3 hrs and was followed by slow cell death (half life = 23.5 hrs). However, unlike its parent (open squares), CH4ts (open circles) stopped growing within 3 hrs of being placed in the presence of glucose (solid lines) and underwent accelerated cell death (half life = 12.1 hrs). This difference correlated temporally with the accumulation of high intracellular concentrations of pyruvate in the mutant (Fig. 2, Panel B).

- 20 -

Example 4: Effect of glucose and temperature upon growth and end-product concentration in CH4ts and NG8 in continuous culture

CH4ts was grown to saturation at 30°C in the reaction vessel of a chemostat. Medium inflow providing a dilution rate of 0.1 hr⁻¹ was maintained for 72 hrs before the temperature of the culture was shifted to 42°C. Within 3 hours, the cell density began to decline at a rate equivalent to the theoretical washout rate, indicating a cessation of cell growth (Fig. 3). This correlated with an increase in the glucose concentration observed in the reaction vessel.

When the continuous culture experiment was repeated using a dilution rate of 0.006 hr⁻¹, stable growth of CH4ts was achieved when the temperature was shifted to 42°C (Fig. 4). Immediately following the temperature shift, lactic acid concentrations declined in agreement with the predicted washout rate. Cessation of lactate production was accompanied by initiation of ethanol and acetoin production, resulting in a gradual increase in the pH of the continuous culture. Glucose concentrations remained undetectable throughout the experiment.

These data show that stable growth of CH4ts at 42°C can be achieved in continuous culture under glucose-limiting conditions. Under glucose-limiting conditions, CH4ts behaved like chemically-derived LDH-deficient mutants of *S. rattus* (Hillman et al., 1987, *Infect. Immun.*, 55:1399-1402) with respect to increased ethanol and acetoin production in place of lactic acid production. These results accord with fermentation and enzymology studies indicating that *S. mutans* has regulated, alternate pathways for pyruvate metabolism. Under appropriate conditions of cultivation, wild-type *S. mutans* produces substantial amounts of formate, acetate, ethanol and acetoin (Yamada et al., 1975, *J. Bacteriol.*, 124:55-61; Hillman et al., 1987, *Infect. Immun.*, 55:1399-1402) in addition to lactate. However, these alternate pathways are apparently insufficient to compensate for the absence of LDH activity.

Example 5: Production of ADH rescues LDH⁻ lethality in *S. mutans*

E. coli strain DH5α transformed with pADH, which contains the *Z. mobilis adh* open reading frame fused to the *S. mutans spaP* regulatory sequences, expressed the cloned ADH activity (specific activity 6.95 μmol/min/mg protein). This result agreed

- 21 -

with previously published data indicating that the *spaP* promotor and ribosome binding site (rbs) are active in *E. coli* (Lee et al., 1988, *Infect. Immun.*, 56:2114-2119). The level of ADH activity was approximately 17% of that found in DH5 α transformed with pLOI286 (specific activity 41.8 μ mol/min/mg protein), which has the original cloned *adh* gene and regulatory sequences from *Z. mobilis*. Interruption of the ampicillin resistance gene on the pCR2 backbone by insertion of the tetracycline resistance gene from pVA981 (pADH-tet) did not affect the level of ADH activity.

One microgram of pADH-tet was used to transform CH4ts. Campbell type recombination installed the *spaP::adh* fusion into the chromosome of CH4ts. The site of insertion was not identified, but likely is at a region of homology provided by either *spaP* or the endogenous *adh* gene. Transformed CH4ts were selected for growth at 42°C on medium containing tetracycline. From several hundred clones which arose, one purified isolate called CH4ts::adh contained substantially more ADH activity (specific activity, 60.43 μ mol/min/mg protein) than its wild-type grandparent NG8 (specific activity, < 1.0 μ mol/min/mg protein).

CH4ts::adh and NG8 were grown at 42°C for 48 hrs in Todd-Hewitt broth supplemented with 2% glucose. Cell-free culture liquors of CH4ts::adh had a significantly higher pH (4.7) and ethanol content (21.60 mM) than did culture liquors of NG8 (4.0 and < 1 mM). Identical results were obtained when higher (5, 10 or 20%) concentrations of glucose were used.

The growth of CH4ts::adh at 42°C in defined medium supplemented with 0.5% tryptone and various carbon sources at 1% was compared to NG8 (Table 1).

TABLE 1. Growth properties of wild-type and ADH-complemented LDH-deficient *S. mutans*

Carbon Source	Doubling Time (hr)		Yield (O.D. ₅₅₀)		Lactate (mM)		Ethanol (mM)	
	NG8	CH4ts::AD H	NG8	CH4ts::AD H	NG8	CH4ts::AD H	NG8	CH4ts::AD H
glucose	2.1	2.0	0.94	1.08	20.1	0	1.4	21.2
galactose	4.8	2.4	0.68	0.99	19.3	0	1.3	18.9
lactose	1.9	2.2	0.95	1.03	19.9	0	0.1	19.9
mannitol	4.5	2.0	0.36	0.94	5.9	0	4.5	26.2
sorbitol	8.0	3.0	0.35	0.97	3.8	0	3.6	26.1
sucrose	2.6	3.4	0.78	0.74	20.4	0	0	19.7

Results are the average of two independent experiments.

Other fermentation end-products besides lactate and ethanol were not determined.

- 23 -

The rates and cell yields were comparable when glucose, lactose or sucrose served as the carbon source. CH4ts::adh had substantially shorter doubling times and higher yields than NG8 when galactose, sorbitol or mannitol served as the carbon source. No lactic acid was detected in culture liquors of CH4ts::adh grown on any 5 of the carbon sources, and ethanol was present in much greater amounts than was found in culture liquors of NG8.

These data show that the recombinant *S. mutans* strain CH4ts::adh exhibited 10 substantially higher levels of ADH activity than NG8 wild-type control strain under identical conditions of growth. Moreover, transformants of CH4ts grew at the non-permissive temperature, indicating that the cloned ADH activity circumvented the metabolic blockade caused by LDH-deficiency.

These data further show that the growth rates and growth yields of CH4ts::adh and 15 NG8 are similar when glucose, lactose or sucrose served as the sole carbon source, and growth yields were also comparable. However, NG8 grew poorly on both mannitol and sorbitol under aerobic conditions, but CH4ts::adh grew well. This result indicates that the cloned ADH activity provided sufficient ethanol production to serve 20 as a suitable sink for excess electrons generated during polyol metabolism. NG8 also grew poorly on galactose. It is not clear why CH4ts::adh should grow better than NG8 on this carbon source which is metabolized via the tagatose 6-phosphate pathway in *S. mutans* (Hamilton et al., 1979, *J. Bacteriol.*, 140:1102-1104), particularly since their growth on lactose was comparable.

Example 6: Production of pyruvate decarboxylase does not rescue LDH- lethality in *S. mutans*

A study similar to that described in Examples 2-5 was performed to determine if a 25 defect in LDH could be rescued by production of a pyruvate decarboxylase. The pyruvate decarboxylase (*pdc*) gene from *Z. mobilis* (Conway et al., 1987, *J. Bacteriol.*, 169:949-954) was fused to *spaP* and introduced into CH4ts on a suicide vector as described for the *Z. mobilis adh* gene. Tetracycline-resistant, PDC-expressing transformants were isolated and tested for growth at the non-permissive 30 42°C temperature as described above. LDH⁻ *S. mutans* expressing the cloned PDC activity did not grow at the non-permissive temperature. These results indicate

- 24 -

that the lethality of the LDH⁻ defect in *S. mutans* cannot be rescued by production of PDC. Further, these data indicate that the concentration of ADH was not saturating in the metabolism of pyruvate in LDH-deficient mutants of *S. mutans*.

5 Example 7: Isolation of JH1000 and JH1000 variants producing increased levels of bacteriocin activity

Isolation of the *S. mutans* JH1000 has been described (Hillman et al., 1984, *Infect. Immun.*, 44:141-144). Briefly, JH1000 was identified from fresh isolates of mutans streptococci obtained from 115 subjects on *mitis salivarius* agar containing bacitracin. JH1000 inhibited the growth of all of the other *S. mutans* strains, as well
10 as a large number and variety of laboratory strains in a deferred antagonism assay. Evidence indicates (Hillman et al., 1984, *Infect. Immun.*, 44:141-144) that JH1000 produces a small (less than 1,000 Da), stable antibiotic-like, bacteriocin-like compound which is currently being characterized. This compound is termed
15 *S. mutans* bacteriocin. Microbiological and serological assays confirmed that JH1000 is a representative of the *S. mutans* species. Variants of bacteriocin-susceptible strains, either naturally-occurring or generated by chemical mutagenesis, that are resistant to the killing properties of bacteriocin have not been identified. This result indicates that, unlike most antibiotics, the risk of superinfection by resistant, wild-type (disease-causing) strains is minimal.

- 20 The JH1000 strain was subjected to chemical mutagenesis using ethyl methanesulfonate (EMS) according to methods well known in the art (Hillman 1978, *Infect. Immun.*, 21:206-212). JH1005 is an exemplary EMS-induced variant of JH1000. Variants producing increased levels of bacteriocin were identified by growing a broth culture of the strain to be tested for 8 hrs or more. The culture was
25 centrifuged to remove the bacterial cells, and 20 µl samples of the culture supernatant were serially diluted in wells of a microtiter plate. 100 µl of Top agar containing a target strain (usually *S. rattus* BHT-2, Str^R) and 1 mg/ml streptomycin was added to each well. After incubation overnight, the lowest dilution that prevented growth of the indicator strain was determined.
- 30 Using this overlay method, EMS-derived (JH1005) and spontaneous (JH1140) variants of JH1000 were found which produce approximately 3-fold elevated levels

- 25 -

of the bacteriocin-like activity. JH1000, as well as the JH1000 variants, produce lactic acid, and thus are not suitable for replacement therapies for the prevention and/or treatment of dental caries.

Example 8: Colonization of the human oral cavity by *S. mutans* JH1000 variants

- 5 Colonization of the oral cavity of rodents and humans by JH1000 variants having increased bacteriocin activity has been described (Hillman et al., 1987, *J. Dent. Res.*, 66:1092-1094). Briefly, JH1000 or JH1000 variants were applied to the teeth of human volunteers using an infection regimen which involved a standard dental prophylaxis, followed by brushing and flossing a cell suspension containing about
10 10^{11} JH1000 bacteria or JH1000 variant bacteria.

The level of bacteriocin activity and the ability to colonize the oral cavity were strongly correlated. Over a 1 year period after infection with the JH1005 strain, the indigenous mutans streptococci were gradually replaced by JH1005. In addition, the total numbers of mutans streptococci were significantly decreased in two of the three subjects tested.
15

Example 9: Generation of recombinant mutants of *S. mutans* using transposon mutagenesis *S. mutans* strain

- Plasmid pTV1-OK is a *repA(ts)* derivative of the *Lactococcus lactis* plasmid pWW01 (Leenhouts et al., 1991, *Plasmid*, 26:55-66) for conditional replication in both
20 *S. mutans* and *E. coli*. It possesses a kanamycin resistance gene on the plasmid backbone that is expressed in both *E. coli* and *S. mutans* and the transposon Tn917 which confers erythromycin resistance in *S. mutans*.

The pTV1-OK plasmid was introduced into *S. mutans* strain JH1005, and transformed cells were selected at 28°C on BHI agar containing kanamycin.
25 Transformation of JH1005 with 1 mg of pTV1-OK DNA yielded four kanamycin resistant transformants, which is in agreement with transformation frequencies from earlier experiments (Hillman et al., 1994, *Infect. Immun.*, 62:60-64). Independent pools of Tn917 insertions into host chromosomal DNA were generated by temperature shift (45°C) as described by Camilli et al. (1990, *J. Bacteriol.*, 172:3738-

- 26 -

- 3744) Briefly, saturated cultures grown in the presence of kanamycin at the permissive temperature (28°C) were subcultured 1/50 or 1/100. Following a shift to 45°C and overnight incubation, insertions of Tn917 into the host chromosome were isolated by plating samples on BHI agar containing selective concentrations of erythromycin. It was found that 10⁵ of 10⁹ total colony-forming units retained their resistance to this antibiotic. Ninety of 100 randomly chosen erythromycin-resistant colonies were shown by replica patching to be sensitive to kanamycin. This finding indicated that 90% of the erythromycin-resistant clones were the result of the coincident loss of pTV1-OK and the transposition of Tn917 into the JH1005 chromosome. Southern blot analysis of randomly selected erythromycin-resistant mutants suggested that Tn917 transposition was random and resulted in single chromosomal insertions. Southern blot analysis also indicated that the 10% erythromycin-resistant/kanamycin-resistant clones were the result of replicon fusions which installed the entire pTV1-OK plasmid in the JH1005 chromosome.
- 15 Independent pools of kanamycin-sensitive clones were screened for bacteriocin production, sensitivity to 1% glycine, acid sensitivity, and inability to grow anaerobically on mannitol or in the absence of D-alanine supplementation. Mutants in each category were isolated at frequencies ranging from 1 to 2 x 10⁻³.
- 20 Southern blot analysis of two bacteriocin deficient mutants indicated the existence of at least two unlinked genes involved in bacteriocin production and at least three unlinked genetic loci involved in acid sensitivity. Upon introduction of the Tn917-induced acid sensitive alleles isolated in JH1005 into NG8 via natural transformation, the transposon (encoding erythromycin resistance) was co-inherited with the mutant phenotypes at high frequencies. This linkage indicates that the lesion induced by Tn917 was responsible for the mutant phenotypes. Pools of Tn917 mutants have also been obtained in the naturally transformable strain NG8 with similar transposition frequencies and efficiencies of plasmid loss after temperature shift.
- 25 One gene involved in bacteriocin production has been cloned in *E. coli* using a marker rescue technique. The chromosomal DNA from the mutant was digested to completion with EcoRI (which does not cut within Tn917) and ligated into the EcoRI site in the multiple cloning sequence of pUC19. The library was transformed into

- 27 -

MC1061 with selection for ampicillin resistance, and colonies which arose were replicated onto medium with erythromycin. Two clones which arose were shown to contain plasmid DNA which reacted in dot blot analysis with a Tn917 probe. These plasmids are currently being sequenced using primers which read outward from the 5 erythromycin-proximal and erythromycin-distal ends of Tn917.

This is the successful use Tn917 mutagenesis in *S. mutans* and oral streptococci. Previous failures using constructs such as pTV1 or pLTIV3 (Youngman, 1987, In: Plasmids: A Practical Approach, Hardy, ed., IRL Press, Oxford, pgs. 79-103; Camilli et al., 1990, *J. Bacteriol.*, 172:3738-3744) were attributed to the inability of 10 the plasmid backbones to replicate in *S. mutans*. Using the replicative functions of the *Lactococcus* replicon pWV01Ts, pTV1-OK was found to be stably maintained at the permissive temperature in *S. mutans*, thereby providing sufficient opportunity for 15 Tn917 transposition to occur at the non-permissive temperature. Thus, the method described above can be used to generate auxotrophic *S. mutans* strains, as well as other *S. mutans*-derived strains having desirable phenotypes, for use in the present invention.

Example 10: Construction of an LDH⁺, ADH⁺, bacteriocin-producing *S. mutans* Strain

The *ldh* gene of JH1000 has been cloned and sequenced (Hillman et al., 1990, *Infect. Immun.*, 58:1290-1295; Duncan et al., 1991, *Infect. Immun.*, 59:3930-3934). Briefly, the JH1000 *ldh* gene was cloned into *Escherichia coli* strain MC1061 using 20 pBR322 as the vector. One clone, p10-5, containing the *ldh* gene was identified by hybridization with an oligonucleotide probe deduced from the amino-terminal sequence of the LDH protein purified from JH1000 (Hillman et al., 1990, *Infect. Immun.*, 58:1290-1295). These results were verified by demonstrating JH1000 LDH 25 activity in crude cell-free extracts of the p10-5/MC1061 transformant. The nucleotide sequence of the cloned *ldh* was determined and its regulatory signals and open reading frame deduced. The sequence of the JH1000 *ldh* gene is available from GenBank, accession number M72545 (description LDH SM). The cloned *ldh* gene is inactivated by digesting the p10-5 construct with the restriction enzyme *Hpa*I. This 30 results in the removal of 510 bases from the *ldh* open reading frame, thus permanently inactivating the gene. The appropriate sized DNA fragment from this digestion is recovered by agarose gel electrophoresis, treated with mung bean

- 28 -

nuclease to produce blunt ends, and dephosphorylated by reaction with calf intestinal phosphatase.

The entire open reading frame of the *Z. mobilis adh* gene (except for substitution of the first three bases with a guanidine residue and the addition of a translational and transcriptional codon at the end of the open reading frame) is amplified by PCR. After gel purification, this fragment is treated with mung bean nuclease to produce blunt ends, and phosphorylated by reaction with polynucleotide kinase. This product and the p10-5 product described above are ligated and transformed into *E. coli* DH5 α with selection for ampicillin resistance. Permeabilized cells of purified clones are then screened for ADH activity as described above. Plasmids from ADH positive clones are then purified and checked by restriction mapping to confirm the genetic construct.

One such genetic construct is further modified by elimination of the ampicillin resistance gene on the pBR322 backbone, and replacement with the tetracycline resistance gene from pVA981. This construct is used to transform JH1140, transformants are selected on tetracycline-containing medium. Heterodiploid transformants which arise are purified, grown overnight in Todd-Hewitt broth, and appropriate dilutions spread on glucose tetrazolium medium. After 3 days incubation in candle jars, red colonies which arise, indicating deletion of LDH (or indicating reduced acid production), are isolated and purified as putative LDH-deficient mutants.

The phenotype and genotype of the transformants is confirmed by assaying 2 day old broth cultures for lactic acid and ethanol, by Southern blot analysis, and by spectrophotometric assays of cell-free extracts for LDH activity as described above. The lactic acid production in these strains is expected to be undetectable, while the ethanol content of the medium is expected to be about 25 mM in broth containing 1% or more glucose. The LDH activity of these transformants is expected to be undetectable.

The transformant strains are further characterizations by examining the growth of the parent and transformant on various carbon sources, with and without oxygen. The transformant is expected to grow as well or better than the parent strain in terms of

- 29 -

generation time and cell yield. The parent and transformant strains are also grown in chemostat cultures in order to accurately assess fermentation end-products under different conditions of growth. The transformant strain is expected to produce no detectable lactic acid under all cultivation conditions, and to make significant acetoin only during aerobic incubation.

The cariogenic potential of the transformant is also determined in a rat model of dental caries using conventional and/or germfree rats. The transformant is expected to be virtually non-cariogenic, while the parent strain should produce a high incidence and severity of carious lesions. Plaque production and bacteriocin production by the transformant and parent strain are also assayed.

Where the transformant strain at least minimally satisfies the expectations described above (i.e., is deficient in lactic acid production, and is non-cariogenic), the transformant is a recombinant *S. mutans* strain suitable for use in the prevention or treatment of dental caries.

The following bacterial strains have been deposited on or before June 7, 1995, with the American Type Culture Collection, 1301 Parklawn Drive, Rockville, MD, USA (ATCC).

	<u>Deposit</u>	<u>ATCC Accession No.</u>
	JH1000	ACCESSION NO. 55677
20	JH1140	ACCESSION NO. 55676

This deposit was made under the provisions of the Budapest Treaty on the International Recognition of the Deposit of Microorganisms for the Purpose of Patent Procedure and the Regulations thereunder (Budapest Treaty). This assures maintenance of a viable culture for 30 years from the date of deposit. The bacteria will be made available by ATCC under the terms of the Budapest Treaty and Applicant assures permanent and unrestricted availability of the progeny of the culture to the public upon issuance of the pertinent U.S. patent or upon laying open to the public of any U.S. or foreign patent application, whichever comes first, and assures availability of the progeny to one determined by the U.S. Commissioner of Patents and Trademarks to be entitled thereto according to 35 U.S.C. §122 and the

- 30 -

Commissioner's rules pursuant thereto (including 37 CFR §1.14 with particular reference to 886 OG 638). The assignee of the present application has agreed that if the culture deposit should die or be lost or destroyed when cultivated under suitable conditions, it will be promptly replaced on notification with a viable specimen
5 of the same culture. Availability of the deposited strain is not to be construed as a license to practice the invention in the contravention of the rights granted under the authority of any government in accordance with its patent laws.

The foregoing description of the invention is exemplary for purposes of illustration and explanation. It should be understood that various modifications can be made without departing from the spirit and scope of the invention. Accordingly, the following claims are intended to embrace all such modifications.

1. A recombinant *Streptococcus mutans* strain characterized by a) a deficiency in lactic acid production and b) production of a recombinant alcohol dehydrogenase.
2. The strain of claim 1, wherein the lactic acid production deficiency is due to a defect in the lactate dehydrogenase gene.
3. The strain of claim 1, wherein the recombinant alcohol dehydrogenase gene is a *Zyromonas mobilis* alcohol dehydrogenase gene.
4. The strain of claim 3, wherein the *Zyromonas mobilis* alcohol dehydrogenase gene encodes alcohol dehydrogenase II.
5. The strain of claim 1, wherein the recombinant alcohol dehydrogenase gene is a *Streptococcus ratus* alcohol dehydrogenase gene.
6. The strain of claim 1, wherein the strain is further characterized by production of a bacteriocin.
7. The strain of claim 6, wherein the bacteriocin has a molecular weight less than 1,000 daltons, and has antibacterial activity against a bacteriocin-susceptible *Streptococcus mutans* strain.
8. The strain of claim 1, wherein the strain is a D-alanine auxotroph.
9. The strain of claim 8, wherein the strain is contains a defect in the alanine racemase gene.
10. The strain of claim 1, wherein the strain is derived from JH1000 or a variant thereof.
11. A recombinant *Streptococcus mutans* strain characterized by 1) a deficiency in lactic acid production; 2) production of a recombinant alcohol dehydrogenase; and 3) production of a bacteriocin having antibacterial activity against a bacteriocin-susceptible *Streptococcus mutans* strain.

- 2 21. The method of claim 19, wherein the alcohol dehydrogenase is *Zymomonas*
 1 mobilis alcohol dehydrogenase.
- 2 20. The method of claim 19 wherein the mutation in the lactic acid synthesis
 1 pathway is a defect in the lactate dehydrogenase gene.
- 6 20. The method of claim 19 wherein the mutation in the lactic acid synthesis pathway
 5 introducing a mutation in the lactic acid synthesis pathway.
- 5 19. A method for producing a recombinant *Streptococcus mutans* strain
 4 transforming a *Streptococcus mutans* strain with a gene encoding alcohol
 3 alcohol dehydrogenase, the method comprising the steps:
 2 characterized by a deficiency in lactic acid production and production of a recombinant
 1 A method for producing a recombinant *Streptococcus mutans* strain
18. *Streptococcus mutans* JH1140 having ATCC Accession No. 55676.
17. *Streptococcus mutans* JH1000 having ATCC Accession No. 55677.
16. The strain of claim 15, wherein the strain has a defect in alanine racemase.
15. The strain of claim 11, wherein the strain is a D-alanine auxotroph.
14. The strain of claim 13, wherein the *Streptococcus mutans* JH1000 variant
 2 is *Streptococcus mutans* JH1140 or a variant thereof.
13. The strain of claim 12, wherein the strain is a *Streptococcus mutans* JH1000
 2 variant that produces bacteriocin at an increased level relative to *Streptococcus mutans*
 1 JH1000.
12. The strain of claim 11, wherein the strain is *Streptococcus mutans* JH1000
 2 or a variant thereof.

- 40 -

1 22. The method of claim 19, wherein *Streptococcus mutans* strain produces a
2 bacteriocin having antibacterial activity against a bacteriocin-susceptible *Streptococcus*
3 *mutans* strain.

1 23. The method of claim 22, wherein the *Streptococcus mutans* strain is JH1000
2 or a variant thereof.

1 24. The method of claim 23, wherein the *Streptococcus mutans* JH1000 variant
2 is *Streptococcus mutans* JH1140.

1 25. The method of claim 19, wherein the strain is a D-alanine auxotroph.

1 26. The method of claim 25, wherein the strain has a defect in alanine racemase.

1 27. A method of reducing the incidence or severity of dental caries in a dental
2 caries-susceptible host comprising administering orally to a dental caries-susceptible
3 host a recombinant *Streptococcus mutans* strain having 1) a recombinant alcohol
4 dehydrogenase gene and 2) a deficiency in lactic acid production, in an amount effective
5 for replacement of dental caries-causing *Streptococcus mutans* host strains in the oral
6 cavity of the host.

1 28. The method of claim 27, wherein the recombinant *Streptococcus mutans*
2 strain produces a bacteriocin having antibacterial activity against a bacteriocin-
3 susceptible *Streptococcus mutans* strain.

1 29. The method of claim 27, wherein the lactic acid production deficiency is due
2 to a defect in the lactate dehydrogenase gene.

1 30. The method of claim 27, wherein the recombinant alcohol dehydrogenase
2 gene is a *Zymomonas mobilis* alcohol dehydrogenase gene.

1 31. The method of claim 30, wherein the *Zymomonas mobilis* alcohol
2 dehydrogenase gene encodes alcohol dehydrogenase II.

- 41 -

1 32. The method of claim 27, wherein the recombinant *Streptococcus mutans*
2 strain is a D-alanine auxotroph.

1 33. The method of claim 32, wherein the recombinant *Streptococcus mutans*
2 strain contains a defect in the alanine racemase gene.

1 34. The method of claim 27, wherein the recombinant *Streptococcus mutans*
2 strain is contained in a mouthwash, toothpaste, chewing gum, floss, chewable tablet,
3 lyophil, or culture medium.

1 35. The method of claim 32, wherein the method further comprises administering
2 orally to the host D-alanine in an amount effective to maintain the recombinant
3 *Streptococcus mutans* strain in the oral cavity of the host.

1 36. The method of claim 35, wherein D-alanine is contained in a mouthwash,
2 toothpaste, floss, chewing gum, or chewable tablet.

1 37. A pharmaceutical composition for reducing the incidence or severity of dental
2 caries comprising:

3 a recombinant *Streptococcus mutans* strain having 1) a recombinant alcohol
4 dehydrogenase gene and 2) a deficiency in lactic acid production; and
5 a pharmaceutically acceptable carrier.

1 38. The composition of claim 37, wherein the recombinant *Streptococcus mutans*
2 strain produces a bacteriocin having antibacterial activity against a bacteriocin-
3 susceptible *Streptococcus mutans* strain.

1 39. The composition of claim 37, wherein the lactic acid production deficiency
2 is due to a defect in the lactate dehydrogenase gene.

1 40. The composition of claim 37, wherein the recombinant alcohol
2 dehydrogenase gene is a *Zymomonas mobilis* alcohol dehydrogenase gene.

- 42 -

1 41. The composition of claim 37, wherein the recombinant *Streptococcus mutans*
2 strain is a D-alanine auxotroph.

1 42. The composition of claim 41, wherein the recombinant *Streptococcus mutans*
2 strain contains a defect in the alanine racemase gene.

1 43. The composition of claim 41, wherein the composition further comprises
2 D-alanine.

1 44. The composition of claim 37, wherein the composition further comprises a
2 flavor-enhancing agent.

1 45. The composition of claim 37 formulated as a mouthwash, toothpaste,
2 chewing gum, floss, chewable tablet, lyophil, or culture media.

1 46. A composition for maintenance of a D-alanine bacterial auxotroph in the oral
2 cavity of a host comprising a D-alanine bacterial auxotroph-maintaining amount of
3 D-alanine.

1 47. The composition of claim 46, wherein the D-alanine bacterial auxotroph is
2 a D-alanine *Streptococcus mutans* auxotroph.

1 48. The composition of claim 46, wherein the D-alanine bacterial auxotroph-
2 maintaining amount is from about 0.01 mg/ml to 167 mg/ml.

1 49. The composition of claim 46, wherein the composition further comprises a
2 flavor-enhancing agent.

1 50. The composition of claim 46 formulated as a mouthwash, toothpaste,
2 chewing gum, floss, or chewable tablet.

INDICATIONS RELATING TO A DEPOSITED MICROORGANISM

(PCT Rule 13bis)

A. The indications made below relate to the microorganism referred to in the description on page <u>29</u> , line <u>19</u>	
B. IDENTIFICATION OF DEPOSIT Further deposits are identified on an additional sheet <input checked="" type="checkbox"/>	
Name of depositary institution American Type Culture Collection	
Address of depositary institution (<i>including postal code and country</i>) 1301 Parklawn Drive Rockville, MD 20852 United States of America	
Date of deposit 02 June 1995	Accession Number 55677
C. ADDITIONAL INDICATIONS (<i>leave blank if not applicable</i>) This information is continued on an additional sheet <input type="checkbox"/>	
D. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE (<i>if the indications are not for all designated States</i>)	
E. SEPARATE FURNISHING OF INDICATIONS (<i>leave blank if not applicable</i>) The indications listed below will be submitted to the International Bureau later (<i>specify the general nature of the indications e.g., "Accession Number of Deposit"</i>)	
For receiving Office use only

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US96/09667

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) C12N 1/21, 15/53; A01N 63/00; A61K 7/16
US CL 435/252.3, 172.3; 424/93.44, 50

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 435/252.3, 172.3; 424/93.44, 50

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Computer Search - CA and APS

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A X	HILLMAN, J. D., et al. Cloning And Expression Of The Gene Encoding The Fructose-1,6-Diphosphate-Dependent L-(+)-Lactate Dehydrogenase Of Streptococcus Mutans. Infect. Immun. May 1990, Vol. 58, No. 5, pages 1290-1295.	1-16, 18-50 17
A X	DUNCAN, M.J., ET AL. DNA Sequence And In Vitro Mutagenesis Of The Gene Encoding The Fuctose-1,6-Diphosphate-Dependent L-(+)-Lactate Dehydrogenase Of Streptococcus Mutans. Infect. Immun. November 1991, Vol. 59, No. 11, pages 3930-3934.	1-16, 18-50 17
A X	HILLMAN, J.D., ET AL. Evidence That L-(+)-Lactate Dehydrogenase Deficiency Is Lethal In Streptococcus Mutans. Infect. Immun. January 1994, Vol. 62, No. 1, pages 60-64.	1-16, 18-50 17

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier document published on or after the international filing date	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubt on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)		
"O" document referring to an oral disclosure, use, exhibition or other means	"&"	document member of the same patent family
"P" document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search

24 JULY 1996

Date of mailing of the international search report

02 October 1996 (02.10.96)
